What is claimed is:

1. A method for incrementally backing up data from a logically represented volume on disk media, accessible by a client through a network connection, the client comprising an enterprise database application, said method comprising:

identifying tracks of the logically represented volume that have changed since a last incremental backup operation by reading fresh data indications, (i) wherein each of the fresh data indications corresponds to a track of the logically represented volume and (ii) wherein a given fresh data indication is indicative of whether its corresponding track has been changed since a last incremental backup operation;

identifying files for incremental backup, the identified files comprising blocks saved on a track deemed changed since a last incremental backup operation; and

backing up the identified files from the disk media to sequential storage media through a high speed connection.

- 2. The method according to claim 1, wherein the identified files are backed up in their entirety.
- 3. The method according to claim 2, wherein the acts of identifying tracks, identifying files, and backing up the identified files are performed by a data manager of an enterprise storage platform.
- 4. The method according to claim 2, wherein said fresh data indications comprise flag bits, set to zero or to one, by hardware when a given track is backed up or updated, respectively.
 - 5. The method according to claim 4, wherein said fresh data indications comprise change marks.
- 6. A system for incrementally backing up data from a logically represented volume on disk media, accessible by a client through a network connection, the client comprising an

enterprise database application, said system comprising:

a track identifier to identify tracks of the logically represented volume that have changed since a last incremental backup operation by reading fresh data indications, (i) wherein each of the fresh data indications corresponds to a track of the logically represented volume and (ii) wherein a given fresh data indication is indicative of whether its corresponding track has been changed since a last incremental backup operation;

file identifier to identify files for incremental backup, the identified files comprising blocks saved on a track deemed changed since a last incremental backup operation; and

a backup mechanism to back up the identified files from the disk media to sequential storage media through a high speed connection.

- 7. The system according to claim 6, wherein the track identifier, the file identifier, and the backup mechanism comprise executing portions of encoded computer-readable media of a data manager of an enterprise storage platform.
- 8. The method according to claim 6, wherein said fresh data indications comprise flag bits, set to zero or to one, by hardware when a given track is backed up or updated, respectively.
 - 9. The method according to claim 8, wherein said fresh data indications comprise change marks.
- 10. A machine-readable media for incrementally backing up data from a logically represented volume on disk media, accessible by a client through a network connection, the client comprising an enterprise database application, the computer-readable media being encoded so that, when the machine-readable media is read by a computer, the machine-readable media causes:

identifying tracks of the logically represented volume that have changed since a

last incremental backup operation by reading fresh data indications, (i) wherein each of the fresh data indications corresponds to a track of the logically represented volume and (ii) wherein a given fresh data indication is indicative of whether its corresponding track has been changed since a last incremental backup operation;

identifying files for incremental backup, the identified files comprising blocks saved on a track deemed changed since a last incremental backup operation; and

backing up the identified files from the disk media to sequential storage media through a high speed connection.

- 11. The machine-readable media according to claim 10, wherein the identifying tracks, the identifying files, and the backing up comprise executing portions of encoded computer-readable media of a data manager of an enterprise storage platform.
- 12. The machine-readable media according to claim 10, wherein said fresh data indications comprise flag bits, set to zero or to one, by hardware when a given track is backed up or updated, respectively.
- 13. The machine-readable media according to claim 12, wherein said fresh data indications comprise change marks.
